(54) Tape printing device

(57) Disclosed is a tape printing device that is capable of having set therein any one of a plurality of kinds of tape of different widths for performing printing on the set tape (T). The device comprises printing means (11) having a plurality of heat elements arranged in an array along the width of said set tape (T) wherein the plurality corresponds to the largest one among said different widths. Advancing means (41) are provided for advancing said set tape (T) relative to said printing means (11). Control means (21, 42, 43) are provided for selectively driving said heat elements (11a) and for controlling said advancing means (41) so as to print dots on said set tape (T). The control means (21, 42, 43) is adapted to select, according to the width of said set tape (T), whether the heat elements (11a) used for printing a column of dots along the width of said set tape are to be driven all at once or are to be grouped into a plurality of groups and the groups driven sequentially. Such grouping allows printing on a wide tape even if the power supply to the printing device has a limited capacity as is the case with a battery.

Description

This invention relates a tape printer for printing on a tape recording medium wherein tape recording media of a variety of different widths can be set in the printer.

In recent years, printing devices which print on tape recording media have become very popular. Such tape recording media have on their backs an adhesive layer which is covered with peel-off tape. After printing, the peel-off tape is peeled off and the tape is affixed to a desired place such as a label. Since this kind of printing device (referred to as the tape printer in the present specification) must be small and compact, the printing mechanism used in the printer must also be small. A typical tape printer employs a thermal transfer printing mechanism including a thermal head.

An object of the present invention is to provide a tape printing device capable of printing on narrow tapes as well as wide tapes even when powered from a power supply of limited capacity.

This object is achieved with a tape printing device as claimed in claim 1. Preferred embodiments are subject-matter of the dependent claims.

Other objects and attainments together with a fuller understanding of the invention will become apparent and appreciated by referring to the following description and claims taken in conjunction with the accompanying drawings.

- Fig. 1 shows a perspective view of the tape printer according to the present invention.
- Fig. 2 shows an inside view of the tape printer according to the present invention after the tape cartridge is taken out.
- Fig. 3 is a schematic diagram showing the inside of the tape cartridge.
- Fig. 4 is a schematic block diagram showing the control system of the tape printer according to the present invention.
- Fig. 5 is a schematic diagram of the temperature measuring circuit.
- Fig. 6 is a schematic diagram of the voltage measuring circuit.
- Fig. 7 is a flow chart of the operation for identifying the type of the inserted cartridge and the type of the power supply used.
- Fig. 8 is a flow chart of the operation for controlling the thermal head drive.

- Fig. 9 shows the temporal temperature change of the heat elements of the thermal head when current signals are applied to them.
- Fig. 10 shows the timing of measurement of the temperature during printing.
- Figs. 11A 11C show methods for accelerating the stepping motor.
- Fig. 12 shows the relationships between the tape width, the thermal head drive, and the print speed.
- Fig. 13 shows the relationships between the tape width, the voltage of the power supply, and the print speed.
- Fig. 14 shows the pulse width modulation for the pulse signals for driving the stepping motor.

A detailed description of the present invention for controlling the thermal head drive, as applied to a tape printer, is given below with reference to the accompanying drawings. In the drawings, like reference numerals refer to the like elements.

Fig. 1 is an external view of the tape printer of the present embodiment. A tape printer 1 has a structure similar to a conventional tape printer and includes a case 2, a keyboard 3 on top of it, and a cover 4 with hinges at the rear which opens and closes. A handle 5 is formed in the front part of case 2. Pushing an open button 6 at the center opens cover 4. Cover 4 includes, on one side, a window 4a through which a liquid crystal display located inside is viewed and another window 4b, on the other side, through which a tape cartridge inserted in the cartridge compartment is seen (see Fig. 2).

On one side of case 2 are an AC adapter socket 4c in the rear and a power switch 4d in the front. A battery compartment (not shown) is formed inside case 2, and batteries can be installed or replaced by opening a back cover of case 2. This configuration is the same as the conventional tape printer.

Fig. 2 shows the view as seen when cover 4 is opened. When cover 4 is opened, a compartment 8 for a tape cartridge 7 formed in case 2 is exposed. At the same time a display screen 9a of the liquid crystal display 9, placed next to cartridge compartment 8, is also exposed.

First, the structure of detachable tape cartridge 7 is described with reference to Figs. 2 and 3. The case of tape cartridge 7 comprises an upper case 7a and a lower case 7b. A through hole for the thermal head is formed through both of the cases. Tape cartridge 7 contains a roller 72 for tape recording medium T (referred to

as tape hereinafter) and a roller 73 for an ink ribbon. It also contains a platen roller 74 and a ribbon winding roller 75. The tape T rolled out from tape roller 72 runs along the path shown as a bold broken line in Fig. 3 and exits through an opening 76 on one side of the case. The ink ribbon R runs along the path shown as a bold solid line in Fig. 3 and is laid on top of the tape T at platen roller 74. The ink ribbon R passes along the inner side of through hole 71 and is wound around ribbon winding roller 75.

Printing occurs at platen roller 74 where the tape T comes to lie on top of the ribbon R. A window 71a is formed on the side wall of through hole 71 which faces platen roller 74. An axle insertion hole 72a for positioning is formed at the center of tape roller 72; a roller drive axle insertion hole 74a, at the center of platen roller 74; and another roller drive axle insertion hole 75a, at the center of ribbon winding roller 75.

The front surface of tape T is used for printing and its back side is coated with an adhesive layer which is covered with peel-off tape. Thus, one can stick the printed tape at any place desired by removing the peel-off tape. The printers of the present embodiment are designed to accommodate a tape cartridge containing a tape of either 6, 9, 12, 18, or 24 mm in width.

Tape cartridge compartment 8 for accommodating the tape cartridge has a head unit 12 including a thermal head 11 therein, an axle 13 for positioning, a platen roller drive axle 14, and a ribbon roller drive axle 15 projecting from the bottom of the compartment. When tape cartridge 7 is inserted, the above components mate with through hole 71, tape roller axle insertion hole 72a, platen roller drive axle insertion hole 74a, and ribbon roller drive axle insertion hole 75a, respectively. With tape cartridge 7 inserted, heat elements 11a, arranged in a vertical array on the thermal head surface 11, face the tape T and the ribbon R which run on platen roller 74 through window 71a on tape cartridge insertion through hole 71. Thermal head 11 can rotate from the print position shown in a solid line in Fig. 3 to the release position shown in a fictitious outline and vice versa. In the present embodiment, when cover 4 is closed, a projection 4e formed on the back of cover 4 activates a mechanism (not shown) so that the thermal head moves from the release position to the print position shown in the solid line. Further, pushing open cover button 6 allows thermal head 11 to move back to the release position.

Case 2 includes a tape exit 16 which corresponds to tape exit 76 on inserted tape cartridge 7. The tape T comes out of the printer through both tape exit 76 on the cartridge and tape exit 16 on the case. A cutter (not shown) is included at the tape exit 16, where the tape is cut when a cutter button 17, arranged behind tape exit 16, is pushed down. The mechanism for the cutter is the same as that in the conventional tape printer.

Case 2 also includes a circuit board which controls the operation of each component of the printer, a stepping motor which drives the driving members such as

the platen roller, the ribbon winding roller, etc., and a battery compartment as mentioned earlier.

Next, the control system employed in the printer of the present embodiment is described with reference to Fig. 4. The heart of the control system is a control circuit 20. The control circuit comprises a one-chip microcomputer (CPU) 21, a mask ROM 22, and various circuits which interface CPU 21 with the peripheral circuits. Keyboard 3 and liquid crystal display 9 are coupled, directly or indirectly through interfaces, to CPU 21 and controlled by CPU 21.

A power switch 4d and a cover status detection switch 23 for detecting whether the cover is closed or open are connected to the input ports of CPU 21. A discrimination switch 24 is also connected to CPU 21. Discrimination switch 24 is arranged in one of the bottom corners of cartridge compartment 8. Discrimination switch 24 has three identification switches 24a, 24b, and 24c which fit into three tape identification holes 77 formed on the case of tape cartridge 7. The identification switch generates an "on" signal when the projection of the switch is large, while it generates an "off" signal when the projection is small. Tape cartridges 7 have different combinations of tape identification hole depths (deep or shallow) which vary according to the width of the tape T the tape cartridges contains. Therefore, the output of discrimination switch 24 indicates the tape width contained in the inserted tape cartridge 7. The heat elements of the thermal head are driven differently according to the tape width as described below.

The numeral 25 denotes a power unit. Either an AC adapter 26 or a battery 27 supplies the DC power to the power unit. The input terminals for the DC current are the socket 4c, and the power from AC adapter 26 is supplied by inserting a jack 29. The insertion of jack 29, with the aid of break contacts, breaks the connection of battery 27 with power unit 25. Socket 4c has another contact through which a signal BT is provided to CPU 21.

Based on the BT signal, CPU 21 determines whether the power is supplied by AC adapter 26 or battery 27. The present embodiment employs different print controls depending on the power supply type.

The print density generated by thermal head 11 is a function of the duration of the current signal provided to heat elements 11a, the drive voltage, and the ambient temperature. In the present embodiment, a temperature measuring circuit 31 and a voltage measuring circuit 32 measure the ambient temperature and the drive voltage, respectively. The outputs of circuits 31 and 32 are provided to analog/digital (A/D) conversion input ports AD1 and AD2, respectively. CPU 21 converts the input voltages into digital values and uses them to control the system as shown below.

Temperature measuring circuit 31 of the present embodiment utilizes a thermistor 31a as a temperature sensor as shown in Fig. 5. The voltage difference between the two terminals of the thermistor is supplied

to the A/D conversion input port AD1. The reference voltage for the A/D conversion is equal to the driving voltage V_{cc} for the thermistor. As a result, even if the voltage drops after switching to the battery operation mode, the reference voltage changes accordingly. Therefore the temperature is measured accurately with thermistor 31a regardless of the variation in battery voltage.

Voltage measuring circuit 32 shown in Fig. 6 includes a constant voltage generating circuit 32a which generates a constant voltage when operating within the range of the operation voltages. The generated constant voltage V_0 is input to the A/D conversion input port AD3 of CPU 21. The reference voltage V_{ref} for the A/D conversion is the same as the driving voltage V_{cc} as mentioned above. Even if the voltage of battery 27 drops and the driving voltage V_{cc} changes, the power supply voltage can be measured accurately by referring to the constant voltage V_0 applied to input port AD3 and adjusting the measured voltage accordingly. Thus the present embodiment allows for an accurate measurement of the power supply voltage even when a battery is used as the power supply.

Mask ROM 22 stores various character fonts and is coupled to CPU 21 by means of the address bus and the data bus. Liquid crystal display 9 comprises display screen 9a, a driver for display screen 9a, and a driver controller for controlling driver 9b.

The print mechanism of the printer of the present embodiment comprises thermal head 11 and stepping motor 41 as primary mechanical elements. It also includes a printer controller 42 and a motor driver 43 as primary controlling elements. Thermal head 11 of the present embodiment has 128 heat elements 11a arranged in a vertical array with a fixed interval. The rotation angle of stepping motor 41 is determined by the phases of four driving signals. The tape length advanced with a single step of stepping motor 41 can be adjusted by a reduction mechanism arranged in the case between the stepping motor and the platen roller drive axle. The tape is advanced by driving stepping motor 41 through a fixed number of steps in synchronization with the printing of a one-dot column.

The internal ROM of CPU 21 stores various control programs for driving and controlling the peripheral circuits described above. Executing these programs controls the operation of the system.

Next, the printer operation of the present embodiment is described below. First, Fig. 7 shows a flow chart for identifying the type of the operating power supply and the type of the inserted tape cartridge. Once power switch 4d is activated (Step ST1), the printer determines whether the power supply is AC adapter 26 or battery 27 based upon the signal BT which is the identification signal (Step ST2). The results obtained in the above steps as well as the results to be obtained in the following steps are stored in the working register area of the internal RAM of CPU 21. If the power supply is a battery,

the printer checks to determine whether the battery is installed with the correct polarity (Step ST3). If the printer finds that the polarity is wrong, it detects that an anomaly has occurred, shuts off the power, and finishes the operation (Step ST4). Next, the type of inserted tape cartridge 7 is determined from the signals of discrimination switches (Step ST5). In the present embodiment, there are five types of tape cartridges 7 of different widths. If a tape cartridge is not found there, a warning for abnormal operation is displayed on liquid crystal display screen 9a, the power is shut off, and the operation ceases (Step ST6). Thus, the type of power supply used and the type of inserted cartridge are determined.

Fig. 8 shows the flow chart for controlling the duration of the current signal provided to the heat elements of the thermal head depending upon the ambient temperature of thermal head 11. In the present embodiment, the ambient temperature of the thermal head is measured immediately after power is switched on, and the measured temperature is referred to as T_1 . When the print command is issued, the ambient temperature of the thermal head is measured just before the printing starts, and this temperature is referred to as T_2 . After printing starts, the ambient temperature of thermal head 11 is measured every time a one-dot line is printed, and the measured temperature is referred to as $T_{3(i)}$ (i is a positive integer). As the measured temperature changes, the duration of the current signal provided to the heat elements of thermal head 11 is changed.

Next, the steps for the signal duration control are described below. First, the initialization, described with reference to Fig. 7, is performed after the power is switched on. Then, the initial temperature T_1 of thermal head 11 is measured based on the signal from temperature measuring circuit 31 (Step ST11) and the operation awaits a print command (Step ST12). When the print command is issued, the temperature T_2 is measured just before printing begins (Step ST13). Next, the difference between T_1 and T_2 is computed and compared with a predetermined value T_a to determine whether the difference is greater or less than T_a (Step ST14).

Generally, the temperature of the environment does not change much between the time the power is switched on and the time just before printing begins. Typically the temperature difference is less than about 5°C. Therefore, if, for example, T_a is set at 5°C and if the temperature difference is less than T_a , the temperature T_2 is considered to be the ambient temperature of thermal head 11.

In this case, a loop made with Step ST15 through Step ST19 is executed. That is, the pulse duration provided to heat elements 11a of thermal head 11 is determined for the temperature T_2 in order to form printed dots of the appropriate density. On each printing, i.e., on each pulse applied to thermal head 11, the temperature is measured and stored as $T_{3(i)}$. If $T_{3(i)}$ is higher than the temperature which indicates the overheating of thermal

head 11, the printer detects that an anomaly has occurred, aborts the operation, and shuts off the power (Step ST18 - ST20). The temperature which defines the overheat of the thermal head in steps ST18 and ST28 described below must be determined so that there can be no damage to the thermal head; there can be no adverse effect to the case or other components near the thermal head; and there can be no danger of being burned even when fingers touch the thermal head. The typical preferred temperature is about 70°C.

If the difference between the temperatures T_1 and T_2 is more than T_a , thermal head 11 is considered to have been heated up in the previous printing operations and the ambient temperature is believed to have been affected by the heated thermal head. In this case the ambient temperature is set at the initial temperature T_1 and the pulse duration is determined for that temperature. In other words, the operation moves to step ST21 from step ST14 where the temperature T_2 is stored as $T_{3(i)}$. Then the pulse duration applied to thermal head 11 is determined for the initial temperature T_1 (steps ST22 and ST23). Next, the temperature measurement is performed (step ST24) and the measured temperature is stored as $T_{3(i+1)}$ (step ST25).

Thus in the case in which the difference between temperatures T_1 and T_2 is larger than T_a , the signal duration is determined by the initial temperature T_1 . The thermal head is heated through repetitive printings and may overheat. That is, if the currently measured temperature $T_{3(i+1)}$ is higher than the temperature $T_{3(i)}$ measured during the previous printing by the predetermined temperature T_B , thermal head 11 must not be heated further. The typical value for T_B is about 1°C.

In the present embodiment, if thermal head 11 increases in temperature excessively over the previous printing, the operation moves from step ST26 to step ST15, wherein the signal duration to thermal head 11 is determined for the preprinting temperature T_2 . Typically, since the temperature T_2 is higher than the initial temperature T_1 , the signal duration determined for T_2 is smaller than that for T_1 . As a result, the energy applied to thermal head 11 is reduced and this prevents the thermal head from overheating.

When thermal head 11 overheats after gradually accumulating heat on each printing, the operation detects it from the temperature $T_{3(i)}$ in step ST28, aborts the printing, and shuts off the power (step ST20).

In the present embodiment, the initial temperature T_1 is stored for a specified period of time even after the power is shut off (not shown in Fig. 8). The reason for this is as follows: if the power is switched back on within too short a time after being shut off following a series of printings, thermal head 11 may not have been cooled down sufficiently. Hence the new initial temperature T_1 measured after the power is on does not represent the real ambient temperature of thermal head 11. Therefore, in the present embodiment the initial temperature T_1 is stored for a specified period of time after the power

is shut off during which thermal head 11 can sufficiently cool down. For this purpose an EPROM may be used as a memory means. Thus, when the power is put back on within five minutes, for example, the stored temperature T_1 is used for the new initial temperature (in this case the step of measuring the initial temperature may be omitted). If the printer has an automatic power shut-off feature, the initial temperature can be cleared when the power is shut off by this feature.

The timing for measuring the temperature $T_{3(i)}$ during the above control operation is described below. Fig. 9 shows the temperature change of a heat element of thermal head 11 when pulses are applied to the thermal head. The change depends on the temperature of the heat element before the pulse is applied. Therefore, it is desirable to measure the temperature immediately after the pulse is applied as shown in Fig. 10 in order to control the heat generation of the heat element of the thermal head.

Printer 1 of the present embodiment can start printing before the tape speed becomes constant. In other words, because the printing begins while the stepping motor for tape transportation is being accelerated toward the constant print speed, that portion of the tape that is normally wasted can now be saved. In the conventional scheme, when stepping motor 41 starts, it is accelerated to a constant speed in several steps to avoid an irregular operation as shown in Fig. 11A. The constant speed, referred to as V_p , is a print speed and typically 10 mm/sec. The stepping motor, for example, receives a signal to start at the time t_0 , and is accelerated in five steps to reach the print speed of 10 mm/sec at the time t_2 when the printing actually starts. Since the tape starts running at the time t_0 , the amount of tape advanced during the time period between t_0 and t_2 is wasted.

As shown in Fig. 11B, printer 1 of the present embodiment starts actual printing at the time t_1 before the constant print speed is reached. The motor speed at the time t_1 is V_{p1} , which is slower than V_p . In the present embodiment, after the actual printing starts, the acceleration is set lower than that prior to printing so that the constant print speed V_p is reached at the time t_3 which is later than t_2 . Since the acceleration is set low when the actual printing starts, the printed dots are not deformed. In other words, the acceleration is set so low that the print quality is not degraded. As a result the amount of tape advanced before the real printing (time t_1) is less than that of the conventional scheme and hence less amount of paper is wasted in the present embodiment.

The print speed V_p can be higher, for example 15 mm/sec, than the conventional print speed of 10 mm/sec. In this case, however, acceleration of the motor in five steps may induce an irregular operation of the motor, giving rise to a degradation of the print quality. A solution to this problem is to increase the number of steps. If the motor is gradually accelerated to the

higher print speed, a long time is required before it reaches the print speed. Much paper is wasted. Since printing can start while the motor is being accelerated in the present embodiment; it is possible for the motor to be accelerated first in the conventional way as shown in Fig. 11C, then printing starts at the time t_2 , and the motor is accelerated slowly after the time t_2 . This scheme results in the same amount of wasted tape as the conventional scheme. Thus the present embodiment allows for faster printing while consuming the same amount of wasted tape at the start of printing as does the slower conventional printer.

Similarly, printing can also occur as the motor is decelerating to finish printing. There is no degradation of print quality if the deceleration during printing is sufficiently small.

Next, the print controls of the present embodiment during the use of battery 27 as the power source are described below. Since a battery has a limited capacity, low-power print controls are highly desirable. In the present embodiment different thermal head drive schemes and print speeds (tape speeds) are used for different types of tape cartridges 7.

The thermal head drive scheme for a narrow tape is that all dots of the column are printed at the same time. In the present embodiment thermal head 11 has 128 heat elements 11a arranged in a vertical array and it can be used for tapes of up to 24 mm in width. Therefore, for a tape of 6 mm in width, the narrowest, only a part of the 128 heat elements are used for printing a column of dots at the same time. For a tape of 24 mm in width, however, all the 128 heat elements may be activated at the same time. The drive current is proportional to the number of heat elements active at any one time. Therefore, a higher current is needed to print on a wider tape. In order to keep the drive current low one can print a column of dots either at one time or multiple times according to the tape width as shown in Fig. 12.

For tapes of 6 mm and 9 mm in width, all the necessary heat elements to print the column of dots are driven at the same time. However, for tapes of 12 mm and 18 mm in width, the number of the heat elements necessary to print the column is more, so the elements are divided into two groups which are driven alternately. For example, in the first run, the odd-numbered of the 128 heat elements counting from the top are activated, while, in the next run, the even numbered heat elements are activated. For printing on the widest tape of 24 mm in width, all the 128 heat elements are used to print the column of dots. In this case, the column is printed with three groups of heat elements. In the initial run, the first heat element and every third element thereafter are on; in the second run, the second heat element and every third element thereafter come on; and, in the third run, the third heat element and every third element thereafter are on.

Driving the heat elements in separate groups keeps the drive current low and allows a battery of a limited

capacity to be used for print control.

In the present embodiment, the print speed (tape speed) is changed according to the tape width as shown in Fig. 12. The differences in the print speed reflect the differences in the driving scheme of heat elements 11a of thermal head 11 as described above. The print speed for narrower tapes is faster while that for wider tapes is slower. In the present embodiment, the print speed for the tapes of 6 mm, 9 mm, and 12 mm in width is 15 mm/sec whereas the print speeds for the tapes of 18 mm and 24 mm in width are 10 mm/sec and 7 mm/sec, respectively. Thus, changing the drive scheme according to the tape width allows the printer to print at the different and more appropriate print speed as dictated by varying conditions.

Different drive energy may be provided to the thermal head depending on the tape width. The technique of changing the drive scheme according to the tape width can also be used when the power is supplied by the AC adapter rather than the battery.

When battery 27 is used for the power supply and still has the rated voltage, printing is performed at a speed dependent upon the tape width as shown in Fig. 12. However, when voltage measuring circuit 32 senses a drop in battery voltage V_d , the printing operation is switched to a low power print mode in which the print speed is reduced.

Fig. 13 shows the print speeds as being dependent upon the voltage V_d and the tape width. When the voltage V_d is higher than the switch voltage A, the print speeds are the same as shown in Fig. 12. When the voltage V_d is lower than A but higher than the value B, the highest speed is reduced to 10 mm/sec. When the voltage V_d drops further below the value B but stays above the operable voltage C, all the speeds are reduced to the slowest speed of 7 mm/sec.

Switching to the low power operations as the battery voltage drops prevents the battery from wearing out too soon. It also prevents any degradation of the print quality due to a fluctuation in the print speed as caused by insufficient driving power to the motor and the resultant irregular motor motion.

In the present embodiment a voltage converter is not used for the battery operation, and the source voltage is applied directly to the stepping motor to drive it. Excluding a voltage converter thus contributes to saving power because there is no power loss there. In this case, however, since the battery voltage varies as the battery is used, the voltage rating of the motor must be set at a value lower than that of a new battery. This rating causes a problem when a new battery is used, because, in this case, excessive driving energy is applied to the motor.

In order to overcome this drawback, the present embodiment monitors the power supply voltage using voltage measuring circuit 32. Pulse width modulation, depending on the measured voltage, is performed on the pulse signals for driving the motor and thus the

appropriate drive energy is always applied to the motor.

An example of the pulse width modulation of the motor driving pulse signals is described with reference to Fig. 14. First, saw-tooth signals b of a fixed period are generated as shown in Fig. 14. These signals may be generated by software and the timer included in CPU 21. Next, a threshold voltage a in the figure is determined according to the measured voltage. The threshold is determined every time printing is performed. Shifting the threshold voltage changes the pulse width or the duty ratio (Ton/T) of the motor driving pulse signals c in the figure. The duty ratio is small when the power supply voltage is high, whereas it is large when the power supply voltage is low. As a result a constant driving energy is supplied to stepping motor 41.

The embodiments mentioned above are examples of the applications of the present invention for driving the thermal head of a tape printer. It is understood that the present invention is also applicable to other types of printers than tape printers.

Claims

1. A tape printing device that is capable of having set therein any one of a plurality of kinds of tape of different widths for performing printing on the set tape (T), comprising:
 - printing means (11) having a plurality of heat elements (11a) arranged in an array along the width of said set tape (T), the plurality corresponding to the largest one among said different widths,
 - advancing means (41) for advancing said set tape (T) at a certain print speed relative to said printing means (11),
 - control means (21, 42, 43) for selectively driving said heat elements (11a) and for controlling said advancing means (41) so as to print dots on said set tape (T), and
 - a power supply (25-27),
 - wherein said control means (21, 42, 43) is adapted to select, according to the width of said set tape (T), whether the heat elements (11a) used for printing a column of dots along the width of said set tape are to be driven all at once or are to be grouped into a plurality of groups and the groups driven sequentially.
2. The device according to claim 1, wherein when said control means (21, 42, 43) selects grouping said heat elements (11a), the number of groups is determined according to the width of said set tape (T) such that the number is larger when said width is larger whereas the number is smaller when said width is smaller.
3. The device according to claim 1 or 2 wherein said control means (21, 42, 43) is adapted to control said print speed for a set tape having a first one of said different widths to be higher than that of a set tape having a second one of said different widths, the second width being larger than the first one.
4. The device according to any one of claims 1 to 3 further comprising voltage detection means for detecting the power supply voltage of said power supply (25-27), wherein said control means (21, 42, 43) is adapted to control said print speed in accordance with the width of said set tape (T) and the detected power supply voltage.
5. The device according to claim 4, wherein said control means (21, 42, 43) is adapted to reduce said print speed from a first value, set when said detected power supply voltage is not below a first threshold value (A), in at least two steps to a second value when said detected power supply voltage is below said first threshold value (A), and a third value when said detected power supply voltage is below a second threshold value (B) lower than said first threshold value.
6. The device according to claim 5, wherein said third value of the print speed is the same for all of said different widths.
7. The device according to claim 4, wherein said control means (21, 42, 43) is adapted
 - to reduce said print speed, for a first group of said different widths, from a first value, set when said detected power supply voltage is not below a first threshold value (A), in at least two steps to a second value when said detected power supply voltage is below said first threshold value (A), and a third value when said detected power supply voltage is below a second threshold value (B) lower than said first threshold value,
 - to keep, for a second group of said different widths, said print speed constant as long as said detected power supply voltage is not below said second threshold value (B) and to reduce said print speed when said detected power supply voltage is below said second threshold value (B), and
 - to maintain, for a third group of said different widths, said print speed constant irrespective of said detected power supply voltage.
8. The device according to any one of the preceding claims wherein said power supply comprises a battery (27).

(54) Tape printing device

(57) Disclosed is a tape printing device that is capable of having set therein any one of a plurality of kinds of tape of different widths for performing printing on the set tape (T). The device comprises printing means (11) having a plurality of heat elements arranged in an array along the width of said set tape (T) wherein the plurality corresponds to the largest one among said different widths. Advancing means (41) are provided for advancing said set tape (T) relative to said printing means (11). Control means (21, 42, 43) are provided for selectively driving said heat elements (11a) and for controlling said advancing means (41) so as to print dots on said set tape (T). The control means (21, 42, 43) is adapted to select, according to the width of said set tape (T), whether the heat elements (11a) used for printing a column of dots along the width of said set tape are to be driven all at once or are to be grouped into a plurality of groups and the groups driven sequentially. Such grouping allows printing on a wide tape even if the power supply to the printing device has a limited capacity as is the case with a battery.
